ABSTRACT — Two new species of *Paraplonobia* Wainstein and *Eurytetranychus* Oudemans are described from Iran: *Paraplonobia* (*Paraplonobia*) *flechtmanni* n. sp. from Russian knapweed *Rhaponticum repens* (Asteraceae) and *Eurytetranychus amini* n. sp. from gum bushes *Astragalus gossypinus* (Fabaceae). We describe all life stages of *Eutetranychus orientalis* (Klein) and discuss variation within this polyphagous pest species. A key to all known species of the genus *Paraplonobia* (*Paraplonobia*) is given.

KEYWORDS — Tetranychoidea; taxonomy; key; Eurytetranychini; Hystrichonychini; plant

ZOOBANK — 65B35917-251F-41E0-857D-ED80441BAFDE

INTRODUCTION

The spider mites (Acariformes: Tetranychidae) are the largest and most important family of the super family Tetranychioidea, comprising 1,288 species (Migeon & Dorkeld 2006-2015) and numerous pest species (Jeppson et al. 1975; Baker & Tuttle 1994). Its subfamily, tribe and genus level classification have been built, and modified, by several significant works such as Pritchard & Baker (1955), Wainstein (1960), Meyer (1974, 1987), and Gutierrez (1985). The classification presented in Bolland et al. (1998) is generally followed, with the family classified into two subfamilies each split into three tribes (Bryobiinae: Bryobini, Hystrichonychini, Petrobini; Tetranychinae: Eutetranychini, Tenuipalpini, Tetranychini). Although of practical value, this classification is not necessarily stable. For example, Hernandes & Feres (2013) reinstated the tribe Aponychini (Tetranychinae) from three Eurytetranychinae genera.

In this work we describe a new species of *Paraplonobia* Wainstein, 1960 (Hystrichonychini), a new species of *Eutetranychus* (Eurytetranychini) and redescribe the polymorphic species *Eutetranychus orientalis* (Eurytetranychini) based on all active life stages of the Iranian specimens. This is the first species of *Paraplonobia* recorded from Iran, although another unidentified species was previously reported by Khanjani & Kamali (1998). The genus *Eutetranychus* is represented by two species
in Iran, *Eur. admes* Pritchard & Baker and *Eur. buxi* (Garman), while *Eutetranychus* is known from five species: *Eut. africanus* (Tucker), *Eut. banksi* (McGregor), *Eut. fici* Meyer, *Eut. orientalis* (Klein) and *Eut. palmatus* Attiah (Beyzavi et al. 2013). *Eutetranychus orientalis* is a widespread species found on numerous host plants, on which it is sometimes a pest (Jeppson et al. 1975). The species is polymorphic, varying especially in the form of its dorsal setae (Meyer 1987), and several species are already considered synonyms, which are: *Anychus ricini* Rahman and Sapra, 1940; *Eutetranychus monodi* André, 1954; *Eut. sudanicus* El Badry, 1970; *Eut. Anneckei* Meyer, 1974 (see Bolland et al. 1998). In Iran, it is known from numerous localities and host plants (Beyzavi et al. 2013).

**MATERIALS AND METHODS**

Leaves of plants infested by spider mites were taken to the laboratory for processing. Mites were removed from leaves with a No. 0 paint brush under a stereomicroscope and mounted in Hoyer’s medium. The specimens were measured and drawn by using differential interference contrast microscopy at 1000 × magnification on an Olympus BX51 (Iran) or Nikon Eclipse 80i (Australia) microscope.

Body length measurements represent the distance between tip of gnathosoma to end of idiosoma; width was measured above coxae III; setae were measured from their insertion to their tips; distance between setae was measured as the distance between their insertions. Legs were measured from the base of the trochanter to the pretarsus (base of claws).

The terminology, abbreviations and leg chaetotaxy used in the descriptions follows those of Lindquist (1985). Leg setal counts are presented as “total number of tactile setae and eupathidia (total number of solenidia+number of duplex pairs”). All measurements are given in micrometers and the measurements of the paratypes are given in parentheses after the measurement for the holotype.

**TAXONOMY**

**Subfamily Bryobiinae Berlese**

**Tribe Hystrichonychini Pritchard and Baker**

**Genus Paraplonobia Wainstein**

*Aplonobia (Paraplonobia)* Wainstein, 1960: 140.

*Paraplonobia* (Paraplonobia), Tuttle and Baker, 1968:50.

Type species: *Aplonobia (Paraplonobia) echinopsili* Wainstein, by original designation.

Diagnosis — With the features of the Hystrichonychini plus the following. Three pairs of prodorsal setae (*p1* absent); prodorsum without lobes; ten pairs of dorsal opisthosomal setae (*c1-3*, *d1-2*, *e1-2*, *f1-2*, *h1*, note two pairs of *e* and two pairs of *f* setae present, *d3* and *e3* absent); seta *f2* in dorso-sublateral position (never lateral); body not extremely elongate, usually no more than twice as long as wide (*P. boutelouae* slightly greater than 2 ×); opisthosoma without plates or strong tubercles (weak tubercles in *P. echinopsili*); coxal and coxisternal setal formula usually hypotrichous, not exceeding holotrichous condition of 4-3-2-2; tarsus I with two sets of duplex setae. Claw and empodium pad like.

Remarks — *Paraplonobia* was established as a subgenus of *Aplonobia* by Wainstein (1960). The subgenus was later raised to genus by Tuttle & Baker (1968), although their keys to genera and their generic definition of *Paraplonobia* conflicted. While the key (couplet 17) split the genus *Paraplonobia* (simple peritremes) from *Anaplonobia* and *Neopetrobia* (anastomosing peritremes), their subgenera of *Paraplonobia* had simple or anastomosing peritremes. Those *Paraplonobia* with anastomosing peritremes were the subgenus *Lanella* Wainstein, demoted to subgeneric rank by Tuttle & Baker (1968). Meyer (1974) recognized this problem and removed *Lanella* from *Paraplonobia*, returning *Lanella* to generic rank. She provided an updated diagnosis and considered *Paraplonobia* to include four species: *P. echinopsili* (Wainstein), *P. hiliariae* Tuttle & Baker, *P. myops* (Pritchard & Baker) and *P. tridens* Tuttle & Baker.
Gutierrez (1985) and Meyer (1987) then independently modified the definition of *Paraplonobia* and its related genera. Gutierrez (1985) formed a broader definition of *Paraplonobia* by including under it genera with anastomosing peritremes (*Anaplonobia*) and holotrichous coxal setation (the monotypic *Brachynychus*), thereby demoting these two genera to subgenera. In contrast, Meyer (1987) was more restrictive, and considered *Anaplonobia* and *Brachynychus* as separate genera. Meyer’s (1987) definition of *Brachynychus* was similar to that of Gutierrez (1985), except she also noted that this species has empodial pads and true claws that are equal in length and the claws bear only one pair of tenent hairs (as opposed to the claws being longer and bearing two pairs of tenent hairs). Meyer’s (1987) definition of *Anaplonobia* acknowledged its anastomosing peritremes, but also noted that tarsus I lacks the tectal setae and that the coxal formula is 2-3-1-1 or 2-2-1-1.

Due to widespread use of Gutierrez’s (1985) classification, we follow Gutierrez (1985) here. Our genus and subgenus diagnoses are essentially derived from Gutierrez (1985). This definition of Gutierrez (1985) is used by Bolland et al. (1998) and Migeon & Dorkeld (2006-2015) to create the current membership of *Paraplonobia: Paraplonobia (Anaplonobia) — 28 species; Paraplonobia (Brachynychus) — 1 species; and Paraplonobia (Paraplonobia) — 10 species.

**Subgenus Paraplonobia Wainstein**

Diagnosis — With the features of *Paraplonobia* plus the following: coxal setal formula 2-2-1-1 (i.e. 1b, 1c, 2b, 2c, 3b, 4b); peritremes simple. Anal plate with three pairs of setae, tarsus II with one duplex seta (Smiley & Baker, 1995).

*Paraplonobia (Paraplonobia) flechtmanni* n. sp. (Figures. 1-2)

Zoobank: 8D3CE505-86CB-40AE-B441-F68D5DEF4A01

Diagnosis — Prodorsal shield demarcated by longitudinal, broken striae; dorsal body setae slender, pointed distally, moderately long: setae *c1* extending past bases of *d1*, setae *f1* extending past bases of *h1*; other dorsal setae reaching at least halfway to corresponding seta in next row. Stylophore slightly cleft anteriorly. Leg I almost as long as or slightly longer than body; tarsi III and IV with a duplex setal complex; femora 9-6-4-4; genua 5-5-4-5; tibiae 13(1.9)-9-9-9; tarsi 18(3.9+2dup)-15(1dup)-13(1dup)-13(1dup).

Description. Female — (Figs. 1-2; n=2). Idiosoma elongate. Body length including gnathosoma 608(550), excluding gnathosoma 456(450); width 335 (343).

Dorsum (Fig. 1A) — Median propodosomal shield with broken, longitudinal striae; lateral idiosoma with longitudinal to oblique striae; opisthosoma with transverse striae medially and posteriorly (Fig. 1A). Dorsal setae slender, laterally serrate and pointed distally. Lengths of dorsal setae: *v2* 62(62), *sc1* 45(40), *sc2* 52(46), *c1* 54(52), *c2* 52(48), *c3* 55(52), *d1* 42(47), *d2* 56(53), *e1* 49(50), *e2* 62(59), *f1* 71(72), *f2* 66(68), *h1* 65(65). Distances between dorsal setae: *v2-h1* 406(380), *v2-v2* 67(65), *sc1-sc1* 165(167), *sc2-sc2* 235(237), *c1-c1* 128(133), *d1-d1* 104(95), *c1-c1* 64(63), *f1-f1* 42(38), *h1-h1* 41(36), *c1-d1* 34(46), *d1-e1* 75(85), *e1-f1* 64(74), *f1-h1* 55(56).

Venter (Figs. 1B, C) — Coxisternal area between coxae I-III and behind coxa IV with transverse striae; area between setae *3a-4a* with longitudinal striae and posterior opisthosoma with longitudinal to oblique striae (Fig. 1B). Lengths of setae: *ps1* 17(21), *ps2* 15(24), *ps3* 19(23), *h2* 22(22), *h3* 27(30).

Gnathosoma (Figs. 1B, 1D-F) — Ventral infracapitulum with two pairs of adoral setae *or1* 5 (5) and *or2* 6 (5-6) and one subcapitular seta *m* 37(35). Palp eupathidion *su6* length 6(6), width 1(1), solenidion *ω* length 3(3), width 2(2) (Fig. 1E). Stylophore slightly emarginated anteriorly (Fig. 1D). Peritremes simple and oval-shaped distally (Fig. 1F).

Legs (Figs. 2A-E) — Leg I 626(570); leg II 350(329); leg III 379(366), leg IV 485(452). Leg I almost as long as or slightly longer than body length. Leg segment setal formula as follows: coxae 2-2-1-1; trochanters 1-1-1-1; femora 9-6-4-4; genua 5-5-4-5; tibiae 13(1.9)-9-9-9; tarsi 18(3.9+2dup)-15(1dup)-13(1dup)-13(1dup). Tarsus I and III with solenidia...
FIGURE 1: Paraplonobia flechtmani n. sp. Female: A – Dorsal view; B – Ventral view; C – Genitoanal area; D – Stylophore; E – Palp; F – Peritrems.

of these species, \textit{P. flechtmanni} with longitudinal, broken striae medially instead of legs about as long as or slightly longer than the body. \textit{Rhaponticum repens} (L.) Hidalgo (Asteraceae), Iran: This is confirmed by the examination of females of \textit{P. myops} (Pritchard and Baker, 1955). Of these species, \textit{Paraplonobia flechtmanni} \textbf{n. sp.} is comparable with other \textit{Paraplonobia} with legs about as long as or slightly longer than the body, \textit{i.e., P. hilariae Tuttle & Baker, 1968, P. tridens Tuttle & Baker, 1968 and P. myops} (Pritchard & Baker, 1955). Of these species, \textit{P. flechtmanni} \textbf{n. sp.} resembles \textit{P. hilariae} most closely in having a slightly cleft stylophore and long, slender, pointed dorsal setae. However it differs from \textit{P. hilariae} in: prodorsum with longitudinal broken striae; tarsi III and IV with a distal slender solenidion; and the solenidia on tarsi III-IV are as long as or longer than the tarsal setae, compared with being shorter than other tarsal setae in \textit{P. hilariae}. The presence of duplex setae on leg III-IV in our new species is not the addition of a seta, but instead is the close association of the anterior fastigial seta with the solenidion. This is confirmed by the examination of females of an undescribed Australian \textit{Paraplonobia} that has the same tarsal III-IV setation (14+1\textit{ω}) but lack duplex setae.

**Key to species of Paraplonobia (Paraplonobia)**
*(after Meyer 1987, based on literature)*

1. Stylophore rounded anteriorly .......................... 2
2. Dorsal body setae lanceolate; leg I shorter than body .......................... \textit{P. edenvillensis} Meyer
3. Dorsal body setae slender and pointed distally ....... 4
4. Leg I as long as or slightly longer than body ....... 5
5. Prodorsum with longitudinal striae; tarsi III and IV with a distal slender solenidion .......................... \textit{P. myops} (Pritchard and Baker)
6. First three pairs of dorsocentral setae \((c1, d1, e1)\) about half as long as distances between consecutive setae; posterior opisthosomal setae \((f1, f2)\) shorter than longitudinal distances between their bases .......................... \textit{P. herniaria} (Bagdasarian)
7. Dorsocentral setae \((c1, d1, e1\) and \(f1)\) more than half as long as distances between consecutive setae .......................... 9
8. Prodorsum with small punctuations; ratio \(e1/e1-e1\) 0.78; leg I slightly longer than...
body. \ldots P. tridens \textit{Tuttle and Baker} — Prodorsum with longitudinal striae; ratio c1/c1-c1 0.39; leg I shorter than body. \ldots P. dactyloides \textit{Smiley and Baker}

9. Peritremal ending rounded; prodorsum with a well-marked punctate shield; tibia IV with 8 setae. \ldots P. penicillatus \textit{Chaudhri} — Peritremal ending oval; prodorsum without a well-marked punctate shield; tibia IV with 7 setae. \ldots P. echinopsili \textit{(Wainstein)}

Subfamily Tetranychinae
Tribe Eurytetranychini Reck
Genus \textit{Eutetranychus} \textit{Banks}, 1917; 197.

\textit{Neotetranychus} (\textit{Eutetranychus}) \textit{Banks}, 1917: 197.
\textit{Anychus} \textit{McGregor}, 1919: 644.

Type species: \textit{Tetranychus banksi} \textit{McGregor}, by original designation.

Diagnosis — Dorsal opisthosoma with ten pairs of setae (c1-3, d1-2, e1-2, f1-2, h1), venter with setae h2-3; dorsal setae may be inserted on tubercles; peritremes simple or slightly expanded distally; anal valves with two pairs of anal setae (ps1-2); tarsi I and II each bear a pair of ‘associated setae’ (bases of f1” and ω” touching, or nearly so; not coalesced), true claws pad-like, with tenent hairs, empodium absent or a rudimentary knob.

\textit{Eutetranychus orientalis} \textit{(Klein)}
(Figures 3-9)

Diagnosis — Based partially on \textit{Meyer} (1987). Female: propodosoma with longitudinal striae and with distinct strial lobes; opisthosoma striae transverse, except between setae d1-c1 longitudinal to forming a V- or U-pattern; setae c2, c3, d2, e2, f2 variable in length and form, but longer than setae c1, d1, e1, f1, h1, which are often short; dorsal setae plumose, thickened, but otherwise variable in form: dorsocentral setae c1, d1, e1, f1, h1 tending to be lanceolate, ovate or obovate, and dorsolateral setae and sublateral seta c2 subulate, ob lanceolate or spatulate (but sometimes dorsocentral setae taking form of dorsolateral setae, see \textit{Chaudhri et al.} 1974); dorsal setae inserted on small tubercles; distance c1-c1 and f1-f1 subequal; spermatheca elongated and oval, sometimes with pointed tip; coxae II with one seta; leg setal counts subject to some intraspecific variation, but typically as follows: femora 8-6-3-1; genua 5-5-2-2; tibiae 9(1,ω)-6-6-7; tarsi 15(3,ω)-13(1,ω)-10(1,ω)-10(1,ω). Male: distal bent portion of aedagus shorter than dorsal margin of shaft.

Description — Female (Figs. 3-4; n=156) — Color in life red. Idiosoma broad oval. Body length including gnathosoma 382-462, excluding gnathosoma 292-385; width 275-317.

Dorsum — (Figs. 3A-B). Prodorsum medially with longitudinal striae and with distinct strial lobes (Fig. 3B); area between setae c1-d1 and e1-h1 with transverse striae, striae between setae d1-c1 form a V- pattern, idiosoma with longitudinal to oblique striae laterally; dorsal striae with minute knobs (Fig. 3A). Dorsal setae inserted on small tubercles and vary in length and shape, propodosomal and dorsolateral setae and setae c2, h1 long and ob lanceolate-spatulate, dorsocentral setae (c1, d1, e1 and f1) short and ob lanceolate. Lengths of dorsal setae: v2 41-54, sc1 33-57, sc2 41-54, c1 15-31, c3 40-58, c3 42-51, d1 19-30, d2 39-58, el 18-28, e2 37-54, f1 20-36, f2 37-50, h1 27-41. Distances between dorsal setae: v2-h1 287-369, v2-v2 49-60, sc1-sc1 109-128, sc2-sc2 193-226, c1-c1 48-62, d1-d1 98-122, e1-e1 40-59, f1-f1 44-52, h1-h1 25-41, d1-c1 38-66, d1-c1 40-82, e1-f1 25-55, f1-h1 46-87.

Venter — (Figs. 3C-F). Coxisternal area and behind coxa IV with transverse striae; posterior opisthosoma with longitudinal to oblique striae in an inverse U-shape. Lengths of setae: la 40-49, lb 47-57, lc 49-58, 2b 46-56, 3a 45-52, 3b 47-60, 4a 42-54, 4b 46-58, ag 42-56, gl 31-39, g2 30-35, ps1 10-16, ps2 11-16, h2 17-26, h3 17-25. Spermatheca oval and elongated, and saclus terminally rounded or pointed (Figs. 3E-F).

Gnathosoma (Figs. 3C, G) — Ventral infracapitulum with two pairs of adoral setae and one subcapitular seta m 38-52. Palp eupathidion sui length 7-9, width 2, solenidion ω length 4-5, width 1. Stylophore anteriorly rounded; peritremes with simple bulb distally (Fig. 3A).
**Figure 3:** *Eutetranychus orientalis* (Klein) Female: A – Dorsal view; B – Dorsal pattern; C – Ventral view; D – Genital area; E – Spermatheca (Rounded at tip); F – Spermatheca (Pointed at tip); G – Palp.
Figure 4: Eutetranychus orientalis (Klein) Female: A – Leg I; B – Leg II; C – Leg III; D – Leg IV.
Legs — (Figs. 4A-D). Leg I 320-385; leg II 237-345; leg III 276-349, leg IV 279-400. Legs long; leg I longer than body length. Leg segment setal formula as follows: coxae 2-1-1-1; trochanters 1-1-1-1; femora 8-6-4-4/2; genua 5-5-2-2; tibiae 9(4φ)-6(2ψ)-6(1ω)-7; tarsi 15(3ω)-13(2ω)-10(1ω)-10(1ω). Tarsus I and IV with solenidia Lω” 10-16, Lω” 10-18, Lω” 10-16, \( L\omega” \) 9-13, \( L\omega” \) 10-15, III\( \omega” \) 10-13, IV\( \omega” \) 8-12 and tibia I with \( l\phi ) 10-16.

Male (Figs. 5-6; n=95) — Color in life red. Idiosoma oval. Body length including gnathosoma 367-425, excluding gnathosoma 225-307; width 205-242.

Dorsum (Fig. 5A) — Propodosoma with broken, longitudinal striae medially except anterior of sejugal furrow; opisthosoma with irregular striae medially except area anterior of setae \( d1 \) with transverse striae, posterior opisthosoma with transverse striae, lateral idiosoma with longitudinal to oblique striae (Fig. 5A). Dorsal setae thick, subulate, more slender than body length. Leg segment setal formula as follows: e1-f1 33-50, e1-f1 36-46, h1-h1 93-115, \( \xi \) 8-12, IV\( \omega \) 8-14; tibia I with \( l\phi ) 10-16.

Deutonymph (Fig. 7; n=32) — Idiosoma oval. Body length including gnathosoma 272-322, excluding gnathosoma 205-250; width 195-220.

Dorsum (Fig. 7A) — Prodorsum with longitudinal striae, opisthosoma with transverse striae medially and longitudinal striae laterally (Fig. 7A). Dorsal setae on small tubercles and narrowly lanceolate; lengths of dorsal setae \( v2 \) 37-57, \( sc1 \) 40-64, \( sc2 \) 40-61, c1 18-52, c2 39-65, c3 36-53, d1 18-53, d2 44-62, e1 18-46, e2 38-62, f1 36-54, f2 32-54, h1 28-38. Distances between dorsal setae: \( v2-h1 \) 188-230, \( v2-v2 \) 42-53, \( sc1-sc1 \) 104-187, \( sc2-sc2 \) 129-188, c1-c1 37-53, d1-d1 68-87, e1-e1 33-50, f1-f1 24-37, h1-h1 14-25, c1-d1 25-42, d1-d1 35-55, f1-f1 20-37, h1-h1 24-49.

Venter (Fig. 7B) — Ventral integument with transverse striae; ventral setae simple. Length of setae \( la \) 22-32, \( lb \) 30-40, \( lc \) 29-40, \( ld \) 31-41, \( le \) 24-38, \( lb \) 20-38, \( la \) 22-30, \( lb \) 25-31, \( gc \) 16-29, \( g \) 11-22, h2 11-17, h3 11-18, ps1 8-12, ps2 8-12.

Gnathosoma (Fig. 7C) — Ventral infracapitulum with two pairs of dorsal setae and subcapitular setae \( m \) 23-38. Palp and peritremes similar to female and as indicated in figures 7C and 7A. Eupathidium \( su\) length 6-8, width 1-2, solenidion \( \omega \) length 2-3, width 1.

Legs (Figs. 7D-G) — Leg I 168-208; leg II 153-195; leg III 148-188, leg IV 140-195. Leg segment setal formula as follows: coxae 2-1-1-1; trochanters 1-1-1-1; femora 5-3-2-2; genua 5-5-2-2; tibiae 7(1ψ)-5-5-5; tarsi 13(3ω)-11(1ω)-8-8. Tarsus I and II with solenidia Lω” 4-10, Lω” 5-9, Lω” 7-12, III\( \omega” \) 5-10 and tibia I with \( l\phi ) 6-11.

Protonymph (Fig. 8; n=8) — Idiosoma oval. Body length including gnathosoma 237-295, excluding gnathosoma 177-230; width 165-210.

Dorsum (Fig. 8A) — Prodorsum with longitudinal striae and opisthosoma with transverse striae

(Fig. 8A); peritremes and dorsal setae similar to deutonymph. Lengths of dorsal setae v2 41-45, sc1 41-47, sc2 41-46, c1 33-39, c2 45-53, c3 34-42, d1 36-39, d2 43-50, e1 32-38, e2 38-52, f1 34-41, f2 38-45, h1 25-35. Distances between dorsal setae: v2-h1 165-223, v2-v2 43-50, sc1-sc1 82-120, sc2-sc2 132-160, c1-c1 45-50, d1-d1 64-82, e1-e1 25-37, f1-f1 23-29, h1-h1 17-24, c1-d1 20-53, d1-e1 26-46, e1-f1 19-29, f1-h1 22-30.

Venter (Fig. 8B) — Ventral pattern similar to deutonymph. Length of setae m 20-23. Palp similar to deutonymph and as indicated in figure 8C. Eupathidion su6 length 6-7, width 1, solenidion width 2, length 1.

Legs (Figs. 8D-G) — Leg I 117-150; leg II 125-133; leg III 110-160, leg IV 99-107. Leg segment setal formula as follows: coxae 1-0-0; trochanters 0-0-0; femora 3-3-2; genua 4-2-1; tibiae 5(3)-5-5-5; tarsi 11(2)-10(1)-8-6. Tarsi I and II with solenidia Lω 5-6, Lω′ 6-10, Lω″ 6-8, and tibia I with Lϕ 6-9.

Larva (Fig. 9; n = 2) — Body length including gnathosoma 235, excluding gnathosoma 195; width 165.

Dorsum (Fig. 9A) — Pro dorsum and opisthosoma with transverse striae; dorsal setae long and serrate (Fig. 9A). Lengths of dorsal setae: v2 37-43, sc1 39-42, sc2 30-38, c1 31-34, c2 42-51, c3 32-37, d1 33-38, d2 37-42, e1 34-39, e2 41-46, f1 39-44, f2 38-41, h1 25-32. Distances between dorsal setae: v2-v2 43-50, sc1-sc1 85-90, sc2-sc2 112-122, c1-c1 41-50, d1-d1 56-63, e1-e1 14-22, f1-f1 14-15, h1-h1 10-13, c1-d1 19-37, d1-e1 27-44, e1-f1 15-27, f1-h1 14-23.

Venter (Fig. 9B) — Ventral integument between setae 1a-3a with transverse striae and posterior venter with longitudinal to oblique striae (Fig. 43). Length of setae 1a 19-22, 1b 21-24, 3a 16-22, ps1 8-11, ps2 8-11, h2 8-15, h3 15.

Gnathosoma (Fig. 9C) — Palp as indicated in figure 9C. Eupathidion su6 length 7, width 1, solenidion ω length 2, width 1.

Legs (Figs. 9D-F) — Leg I 108-115; leg II 96-100; leg III 99-107. Leg segment setal formula as follows: coxae 1-0-0; trochanters 0-0-0; femora 3-3-2; genua 4-4-1; tibiae 5(3)-5-5-5-5; tarsi 8(1)-8(1)-8(1)-6. Tarsi I and II with solenidia Lω 8-10, Lω′ 6-7, and tibia I with Lϕ 6-7.

Material examined. Iran — 156 females, 95 males, 32 deutonymphs (DN), 8 protonymphs (PN), 2 larvae (L) as follows. **Kermanshah province:** 4 females, 1 male ex. apricot leaves, *Prunus armeniaca* (Rosaceae), Dalahoo, Banmazaran village, 34°29′N, 46°01′E, 1456 m a.s.l., 29 Oct. and 2 Nov. 2006, A. Babak Fard; 20 females, 4 males, 2 DN, 1 PN ex. fig leaves, *Ficus carica* (Moraceae), Dalahoo, Banmazaran village, 34°29′N, 46°01′E, 1456 m a.s.l., 23 Sep., 29 Oct. and 2 Nov. 2006, A. Babak Fard; 7 females, 1 male, 1 DN walnut leaves, *Juglans regia* (Juglandaceae), Dalahoo, Banmazaran village, 34°29′N, 46°01′E, 1456 m a.s.l., 2 Nov. 2006, A. Babak Fard; 4 females, 1 male, 2 DN ex. black mulberry leaves, *Morus nigra* (Moraceae), Dalahoo, Banmazaran village, 34°29′N, 46°01′E, 1456 m a.s.l., 2 Nov. 2006, A. Babak Fard; 1 female, 8 males ex. plum leaves, *P. domestica*, Dalahoo, Banmazaran village, 34°29′N, 46°01′E, 1456 m a.s.l., 2 Nov. 2006, A. Babak Fard; 1 male, 2 DN ex. peach leaves, *P. domestica* (Rosaceae), Dalahoo, Banmazaran village, 34°29′N, 46°01′E, 1456 m a.s.l., 2 Nov. 2006, A. Babak Fard; 4 females, 1 male, 2 DN ex. black mulberry leaves, *M. nigra* (Moraceae), Dalahoo, Banmazaran village, 34°29′N, 46°01′E, 1456 m a.s.l., 2 Nov. 2006, A. Babak Fard; 1 female ex. plum leaves, *P. domestica*, Dalahoo, Banmazaran village, 34°29′N, 46°01′E, 1456 m a.s.l., 2 Nov. 2006, A. Babak Fard; 1 male ex. almond leaves, *Prunus dulcis* (Rosaceae), Dalahoo, Banmazaran village, 34°29′N, 46°01′E, 1456 m a.s.l., 2 Nov. 2006, A. Babak Fard; 1 female ex. grapevine leaves, *Vitis vinifera* L. (Vitaceae), Dalahoo, Banmazaran village, 34°29′N, 46°01′E, 1456 m a.s.l., 23 Sep., 2006, A. Babak Fard; 1 female ex. quince leaves, *Cydonia oblonga* (Rosaceae), Dalahoo, Banmazaran village, 34°29′N, 46°01′E, 1456 m a.s.l., 2 Nov. 2006, A. Babak Fard; 7 females, 20 males, 3 DN, 1 PN ex. peach leaves, *P. domestica*, Dalahoo, Babajani village, 34°44′N, 46°09′E, altitude 1250 m a.s.l., 23 Sep., 2006, A. Babak Fard; 2 females, 1 male, 7 DN ex. plum leaves, *P. domestica*, Dalahoo, Babajani village, 34°44′N, 46°09′E, altitude 1250 m a.s.l., 2 Nov. 2006, A. Babak Fard; 4 females, 9 males, 1 DN ex. fig leaves, *F. carica*, Dalahoo,

Iranian variant (not in redescription): 6 females as follows. 5 females ex. soil under palm trees, Phoenix dactylifera (Arecaceae), Kerman province, Bam, 29°06’N, 58°21’E, 1050 m.a.s.l., 20 Apr. and 10 May 2010, A. Asad-Abadi; 1 female ex. soil under sweet orange tree, Citrus × sinensis (Rutaceae), Kerman province, Bam, 29°06’N, 58°21’E, 1050 m.a.s.l., 11 Apr. 2010, A. Asad-Abadi; 5 females deposited as slide-mounted specimens in the Collection of the Acarology Laboratory, University of Bu-Ali Sina, Hamadan, Iran; 1 female will be deposited in Queensland Museum, South Brisbane, Australia.

Remarks — The species definition of Eut. orientalis presents one of the most difficult problems in spider mite taxonomy, with few rivals, such as debate surrounding Tetranychus urticae Koch and its synonyms, especially Tetranychus cinnabarinus Dufour. While that debate is largely resolved thanks to a greater research effort into the problem (Xie et al. 2008; Mendonça et al. 2011; Auger et al. 2013), the difficulties surrounding Eut. orientalis have not received similar research effort, probably because it is a less important pest species. The problem may be more complex, because Eut. orientalis shows more intraspecific variation than species of Tetranychus. Due to this variation the species already has four synonyms (Anychus ricini, Eut. annekei, Eut. monody, Eut. sudanicus) and we suspect several more exist, pending examination of types. In the absence of molecular evidence of a cryptic species complex, we think it best to consider a broad morphological concept for this species.

The most striking intraspecific variation is in the form of the setae, which vary in length and in shape (subulate, narrowly to broadly lanceolate, spatulate, ovate or obovate). This variation was reported in Baker & Pritchard (1960), who provided the first synonymy (Eut. ricini), and Chaudhri et al. (1974) provided a series of drawings showing remarkable variation. As noted by Baker & Pritchard (1960), and confirmed by later observation and personal observation of specimens, they can vary within populations and also asymmetrically on the same specimen. Despite this variation, some generalisations can be made. The setae are always heavily barbed, so much as to be plumose, and the dorsocentral setae (c1, d1, e1) are often small, and are always smaller than the lateral setae and sublateral seta c2. The dorsocentral setae are usually lanceolate, ovate or obovate; while the lateral setae are subulate (thick but tapering) to spatulate (i.e. long, with lanceolate tips). We have not yet found specimens with dorsocentral setae as long as those shown in Chaudhri et al. (1974), but considering the variation we have observed, such variations are not unexpected.

Gutierrez & Helle (1971) conducted crossing experiments and suggested that Eut. orientalis represented a species complex, yet future work has been unable to prove a species complex exists. Meyer (1974) concurred with Baker & Pritchard (1960) that setal length and form should be dismissed as a useful character to separate species within Eut. orientalis, but did consider the pattern of striae between d1-e1 diagnostic, and also the length of the terminal palp sensillum s1C relative to the solenidion ω. On this basis, Meyer (1974) established the species Eut. annekei. However, Meyer (1987) broadened the species concept for Eut. orientalis and rejected the striaion pattern between d1-e1 as diagnostic because this state varied within populations, being U-shaped, V-shaped or entirely longitudinal. Thus, she synonymized her species Eut. annekei with Eut. orientalis and also considered Eut. monodi and Eut. sudanicus as synonyms of Eut. orientalis.

Meyer’s (1987) broader diagnosis comprised two states not included in our diagnosis above: the palp tarsus eupathidion s1ξ, equivalent to the spinneret in web-spinning spider mites, is about three times as long as wide, and setae c1, c2 and c3 in a transverse line. Each of these character states are subject to significant variation and are not used in our diagnosis. First, the palp sensillum was indirectly considered to vary by Meyer (1987) when she synonymized the species Eut. annekei, Eut. monodi and Eut. sudanicus. Our studies have shown similar variation, with the sensillum about 3-4 times longer than wide. Second, setae c1, c2 and c3 do
not form a perfect line, with c2 often anterior of that line, and the character state is likely used to distinguish species with setae c2 anterior and lateral, such as *Eut. cratis* Baker & Pritchard.

Leg setae are also used to define the species, but these vary intraspecifically in *Eut. orientalis*. To explore leg setal variation in *Eut. orientalis*, we examined the setal counts on the femur, genu and tibia of 26 female specimens from Australia and 50 specimens from Iran. These leg segments are often used to distinguish species. For the Australian specimens, only two had the typical setal count of femora 8-6-3-1; genua 5-5-2-2; tibiae 9(1ϕ)-6-6-7. Of the remaining 24, there was one setal difference in 12 specimens, two differences in 7 specimens and three differences in 5 specimens. These differences were mostly asymmetrical (32 of 39 anomalies), with the typical number of setae always expressed on the other side. In the cases of symmetrical differences, these were additional setae on femur III (n = 2) and tibia II (n = 1) and the absence of a seta on femur I (n = 1); the other three symmetrical differences were the expression of three solenidia on tibia I (n = 1) and two solenidia on tibia II (n = 2). Another two specimens expressed solenidia asymmetrically: one with 3/4 ϕ on tibia I (partial male condition) and one with 0/1 ϕ on tibia II (partial male condition). Differences in tactile setal counts are summarized as follows: femur I with 8/9 setae (n = 1), 7 setae (n = 1), femur II with 6/7 setae (n = 1), femur III with 3/4 setae (n = 11), 2/3 setae (n = 1), 4 setae (n = 2), femur IV with 1/2 setae (n = 2); tibia I with 9/10 setae (n = 3); tibia II with 6/7 setae (n = 2), 7 setae (n = 1); tibia III with 6/7 setae (n = 1); tibia IV with 7/8 setae (n = 3).

The Iranian specimens also showed considerable variation, but much less so that the Australian specimens. Of the 50 specimens, 24 had the typical setal count. Of the remaining 26, there was one setal difference in 21 specimens, two differences in 2 specimens and three differences in 3 specimens. These differences were mostly asymmetrical. Differences in tactile setal counts are summarized as follows: femur I with 7/8 setae (n=1), femur II with 6/7 setae (n=2), femur III with 3/4 setae (n=7), 4 setae (n=8), femur IV with 1/2 setae (n=3), 2 setae (n=2); genu II with 4/5 setae (n=5); tibia III with 5 setae (n=1), tibia IV with 6/7 setae (n=5).

Overall, the genual setal counts were stable, with just one specimen with an additional seta on genu III. In contrast, the other leg segments were much more variable. This data shows that variation should be expected on the femora and tibiae of *Eut. orientalis*, especially femur III, which accounted for almost one third of variation. We stress that leg setation remains useful in defining species of *Eutetranychus*, but several individuals from different populations should be examined to establish species definitions. Species of *Eutetranychus* described from few individuals, or just one collection, should be treated with skepticism.

Initially, we considered the possibility that the Iranian specimens of *Eut. orientalis* found on date palm represented a different species, as they differed in spermathecal shape (spermatheca pointed, instead of rounded in other Iranian specimens and in other descriptions), presence of pores between d2-e2, aedeagal shape (subtle differences in shape), and palp tarsal sensillum, presence of pores between d2-e2, aedeagal shape (subtle differences in shape), and palp tarsal sensillum dimensions. However, examination of Australian *Eut. orientalis* showed that the spermatheca can be pointed or rounded, and the pores are always present in *Eutetranychus*, and probably all spider mites; they are simply not drawn in many descriptions. The aedeagus is subject to some variation, which may be intra specific or – more likely – varies according to focal point and orientation during slide mounting, as shown for *Tetranychus* in Seeman & Beard (2011). We note that species of *Eutetranychus* differ little in aedeagal morphology, unlike some other spider mite genera, and most species have a thick, upward-curved prong. Finally, as noted above, the dimensions of the palp sensillum are subject to some variation, and only striking and consistent differences in this character state should be used to define species.

The specimens collected from date palm presented a more compelling reason to consider these a new species. These five females were the only specimens collected from date palm, and unlike the numerous other specimens collected from other plants,
TABLE 1: Range of selected measurements for *Eutetranychus orientalis* on date palm, other Iranian specimens, and Australian specimens. Measurements in bold highlight the larger range of either the specimens from date palm or the other Iranian specimens. Measurements for the Australian specimens are given for comparison.

These specimens had a different dorsal strial pattern, being more U-shaped, and seven setae on femur II. However, as shown by Meyer (1987), differences in strial patterns constitute intraspecific variation in *Eut. orientalis*. Furthermore, examination of variation demonstrated that femur II had variable leg setation, including one specimen with seven setae expressed symmetrically (six is the usual number). Although all five specimens had seven leg setae, expressed symmetrically, it is possible these specimens represented a small founding population where seven leg setae had become fixed. The specimens also differed in several measurements, but the ranges of measurements were not completely exclusive of those of *Eut. orientalis* (Table 1). Generally, the body was shorter, as were several body setae, especially on the venter. The tendency for smaller dimensions, and absence of immature stages, may suggest these mites were a small population struggling to exist on a non-preferred host plant, although Chaudhri *et al.* (1974) also recorded the species from date palm. The Australian specimens also had overlapping ranges with both the *Eutetranychus* from palms and those from other host plants in Iran. Finally, we note that there was no variation in the number of coxal setae in any specimens, which is an important character state that separates *Eutetranychus africanus* (Tucker) from *Eut. orientalis*.

**Tribe Eurytetranychini Reck**

**Genus *Eurytetranychus* Oudemans**

*Eurytetranychus* Oudemans, 1931:224.

Type species: *Tetranychus latus* Oudemans (= *Neotetranychus buxi* Garman)

Diagnosis — Modified from Meyer (1987). Dorsal opisthosoma with ten pairs of setae (*c₁-3, d₁-2, e₁-2, f₁-2, h₁*), venter with setae *h₂-3*; dorsal setae may be inserted on tubercles; peritremes simple or slightly expanded distally; anal valves with two pairs of anal setae (*ps₁-2*); tarsi I and II with or without a pair of ‘associated setae’ (bases of *ft”* and *ω”* touching but not coalesced), true claws pad-like, with tenent hairs, empodium small and claw-like but distinct.

Remarks — *Eurytetranychus* spp. are closely related to *Eutetranychus*, differing only in the size of the empodium, which is small and claw-like in *Eutetranychus* but absent or vestigial in *Eutetranychus*. Meyer (1987) diagnosed the genus as having a pair of associated setae on tarsus I, which are homologous to the duplex setae, i.e., the anterior fastigial seta *ft’* and solenidion *ω’. However, species of *Eurytetranychus* differ in how closely this seta and solenidion associate, and in some species they are clearly separate.

**Eurytetranychus aminii** n. sp.  
(Figures 10-11)

Zoobank: 553B2463-BA28-4D9E-BB48-A92F814D97D3

Diagnosis — Prodorsum with folded transverse striae medially and longitudinal striae laterally; dorsal setae narrowly lanceolate; dorsocentral setae (c1, d1, e1 and f1) as long as or longer than longitudinal intervals between them. Leg segment setal formula: femora 9-7-4-2; genua 5-5-3-2; tibiae 9(1-ϕ)-8-9-9; tarsi 13(3ω)-13(2ω)-10(1ω)-10(1ω).

Description — Female (Figs. 10-11; n= 4) — Idiosoma broad oval. Body length including gnathosoma 362 (382-402); width 370 (357).

Dorsum (Figs. 10A-B) — Prodorsum with folded transverse striae medially and longitudinal striae laterally; opisthosoma with transverse striae medially and longitudinal striae laterally (Fig. 10A). Dorsal setae barbed, thickened, subulate, inserted on small tubercles (Fig. 10B). Lengths of dorsal setae: femora 92 (78-92), genua 52 (48-56), tibiae 9(1-ϕ) 8-9-9; tarsi 13(3ω) 13(2ω) 10(1ω) 10(1ω).

Material examined — Holotype female and 3 female paratypes ex. gum bushes, *Astragalus gossypinus* Fisch. (Fabaceae), Iran: Kurdistan province, Qorveh, 35°10’N, 47°49’E, 1915 m.a.s.l., 10 Oct. 2013, F. Amini. The holotype female, two female paratypes will be deposited as slide-mounted specimens in the Collection of the Acarology Laboratory, University of Bu-Ali Sina, Hamadan, Iran and two paratypes female will be deposited in Queensland Museum, South Brisbane, Australia.

Etymology — This species is named for Mrs. Fatemeh Amini, who collected the type specimens of the species.

Remarks — Many species of *Eurytetranychus* are poorly described and lack diagnostic information, such as dorsal striation patterns. The better descriptions of Pritchard & Baker (1955), Gutierrez (1966), Meyer (1974, 1987) and Ehara (1980) are certainly adequate, but we note that the venter of a species of *Eurytetranychus* is illustrated here for the first time, even though *Eur. aminii* n. sp. is the 19th species of this genus. Therefore, our decision to create a new species is affected by the quality of prior descriptions, and the two main distinctive character states of *Eur. aminii* n. sp. — the prodorsal striae and associated setae on tarsus I — could not be assessed completely.

**Eurytetranychus aminii** n. sp. lacks associated setae because solenidion ω' and setae ft' are well-separated from each other. Likewise, the descriptions of *Eur. admes* Pritchard & Baker and *Eur. wuyishanensis* Hu & Chen show that these species do not have these setae associated (Pritchard & Baker 1955; Hu & Chen 1994). In contrast, ω' and ft' are associated in the descriptions of *Eur. buxi*, *Eur. cyclohalanopsis* Hu & Chen, *Eur. neobuxi* Meyer and *Eur. spathatus* Meyer (Pritchard & Baker 1955; Meyer...
FIGURE 10: Eurytetranychus aminii n. sp. Female: A – Dorsal view; B – Dorsal setae; C – Ventral view; D – Genitoanal area; E – Palp.
FIGURE 11: Eurytetranychus aminii n. sp. Female: A – Leg I; B – Leg II; C – Leg III; D – Leg IV; E – Empodium and claws.
1974; Hu & Chen 1994). These setae are also probably associated in Eur. acacia Meyer and Eur. madagascariensis Gutierrez because Meyer (1987) examined these species and her diagnosis for Eurytetranychus includes the presence of associated setae on tarsus I.

Previous work on Eurytetranychus used the form and size of body setae, and leg setal counts, to distinguish species. Few other diagnostic states, if any, are used within the genus. As pointed out in the case of Eut. orientalis (see above, and also Gutierrez (1977) and Meyer (1987)), tetranychid mites are not always morphologically conservative, especially in body setae shape and size, and leg setal counts. Eurytetranychus is no exception, as Eur. neobuxi Meyer varies in leg setal counts (Meyer 1987). Indeed, polymorphic dorsal setae and leg setal variation may be widespread in the Eurytetranychini and Aponychini. For example, Hernandez and Feres (2013) provided evidence of intraspecific variation in the Aponychini, suggesting numerous synonyms exist in the group. We conclude the same is likely in Eurytetranychus and Eutetranychus.

In addition to polymorphism in dorsal setal form and intraspecific variation in leg setal counts, we must also rely upon the accuracy of past descriptions in the absence of easily-accessed type specimens or quality data on these types. However, despite our reservations, we describe this new species because of its unusual transverse central dorsocentral striae, lack of associated setae, the fact that it cannot be easily accommodated within any other species of Eurytetranychus, occurs on a novel host for the Eurytetranychini (Migeon & Dorkeld 2006-2015), and also provides morphological data hitherto absent for this genus.

As mentioned above, the new species does not match any of the reasonably well-described species of Eurytetranychus due to the transverse central dorsocentral striae. Of the remaining species, Eur. aminii n. sp. resembles E. huaqingnicus Ma and Yuan and E. fengchengensis Ma and Yuan by sharing tapering dorsal setae, setae d1 and e1 longer than the longitudinal intervals between them and femur III with four setae (Ma & Yuan 1981). However E. aminii n. sp. differs from E. huaqingnicus by: tibiae II and III with nine setae in new species whereas seven setae in E. huaqingnicus; femur IV with two setae in E. aminii versus three setae in E. huaqingnicus; and setae f1 versus three setae (setae c1 ca. 1.25 times longer than h1 in new species instead of four times longer in E. huaqingnicus.

Eurytetranychus aminii n. sp. differs from the E. fengchengensis by: setae c1 longer (setae c1 0.8-0.9 as long as distance between setae c1-c1) in the new species but shorter (setae c1 ca. 0.5 distance c1-c1) in E. fengchengensis; tarsi II and IV with 15 and 11 setae respectively in new species but 14 and 10 setae in E. fengchengensis; and tibiae II and III with nine setae in new species whereas with seven setae in E. fengchengensis.

The morphological variation present within this group, coupled with substandard species descriptions, compels us to urge caution with the use of the key below. Within Eurytetranychus, we also suggest several "species groups" that may instead be groups of synonymous species, pending examination of type specimens. These are numbered as follows, with a comment on the likelihood of these species being synonyms in square brackets. Each group is based on the form and size of the dorsal setae only as this is shown in most descriptions, but this makes the assumption that dorsal setae are not polymorphic. While polymorphic setae occur in some other Eurytetranychini, they are not yet known for Eurytetranychus, so these groups may be of some help in identifying species.

Group 1 – Dorsocentral setae (c1, d1, e1, f1) long and slender, extending beyond bases of next row of setae. Eurytetranychus ulmi (on Ulmus sp.).

Group 2 – Dorsal setae long and slender, extending beyond bases of next row of setae, except setae c1 shorter. Eur. fengchengensis, Eur. huaqingnicus [on Ulmus sp.] based on only 2-3 females; very high chance of being synonyms of Eur. ulmi.

Group 3 – Dorsocentral setae (c1, d1, e1) short (setae length c1<d1<e1), less than two times shorter than dorsolateral setae and h1, setae f1 the longest. Dorsal setae lanceolate and serrate, not inserted on tubercle with the exception of setae f1,f2 and h1 set on tubercle. Eur. shenyangensis and Eur. acaciae.

Group 4 – Dorsocentral setae (c1, d1, e1) short (setae length c1<d1<e1) and more than two times
shorter than dorsolateral setae. Dorsal setae slender and serrate set on tubercles. *Eur. koreanus*.

Group 5 – Dorsal setae of moderate length, most or all opisthosomal extending about half-way or more than half-way to next row of setae. *Eur. glycyrrhizae, Eur. aminii n. sp., Eur. buxi, Eur. madagasariensis, Eur. neobuxi, Eur. recki.* [various host plants; *Eur. recki* with thickened setae; *Eur. madagascariensis* and *Eur. neobuxi* are differentiated by small differences in dorsal setal length and palpal sensillar size, so are a chance of being synonyms].

Group 6 – Dorsal setae very small, slender. *Eur. mexicanus* on *Cupresus sp.* and *Eur. admes, Eur. furcisetus, Eur. piceus* on *Piceus spp.* These species (*Eur. admes, Eur. furcisetus, Eur. piceus*) have a high chance of being synonyms, especially *Eur. furcisetus* and *Eur. piceus*, which are European. Unfortunately, the description of *Eur. piceus* is baffling in its lack of detail of even the most basic character states, but detailed examination of insignificant parts of the mite’s morphology.

Group 7 – Dorsal setae of different length, lanceolate and serrate, lateral setae and setae *f1* long, dorsocentral setae short and setae *d1* the shortest. *Eur. cyclobalanopsis* [on *Quercus glauca*].

Group 8 – Dorsal setae of different lengths and forms, lateral setae and *f1, h1* long and lanceolate, dorsocentral setae (*c1, d1, e1*) and *sc1, c2* short and spatulate. *Eur. wuyishanensis*.

Group 9 – All dorsal setae very small and spatulate. *Eur. spathatus*.

**ACKNOWLEDGEMENTS**

The authors wish to thank Prof. Dr. Carlos Flechtmann, Departamento de Entomologia e Acarologia (LEA) (ESALQ), University of São Paulo, São Paulo, Brazil, for supplying literature. This article is a part of the Ph. D thesis program in Agricultural Entomology and was supported by the University of Bu-Ali Sina, Iran. The authors thank the vice presidency for research of Bu-Ali Sina University for financial support of this project.
